

Apple Retail Sales: Where Is Revenue Coming From, and Where Are We Losing Money?

A review of **1,040,199 customer purchases** across **75 stores** and **89 products**, aimed at identifying what's working well and where the business should focus attention.

About This Analysis

This analysis is based on a large dataset of Apple retail transactions including what was purchased, where, and any related warranty claims.

Before drawing conclusions, the data was carefully checked for duplicate records, missing information, and clearly invalid entries such as negative quantities. No such issues were found, and the checking process itself was tested and confirmed to work correctly.

Data quality check completed

The records were reviewed for common data problems, and the checks were deliberately tested using incorrect sample data to make sure they detected problems as expected.

Revenue Has Been Stable, With One Month That Needs a Closer Look

Month over month, revenue has consistently stayed in a steady range of roughly **\$100 million to \$110 million**, showing no major growth or decline over the period covered. There is one sharp drop in the very last month shown this is most likely because that month's data was still being collected when this analysis was run, rather than a real drop in sales.

No Single Product Dominates Revenue Is Spread Across a Wide Range

Looking at the ten highest-earning products, their revenue totals are remarkably close to one another, meaning the business isn't relying on one "hit" product to drive sales. Notably, the single top earner is **Apple Music**, a subscription service rather than a physical device suggesting subscription revenue is a stronger contributor than many might assume. This is a healthy sign: the business is diversified and not overly dependent on any one item.

Warranty Claims Are Consistent Across All Product Categories

Across every product category, roughly **3 out of every 100 sales** resulted in a warranty claim, with very little variation between categories. This consistency suggests there is no single product category with a notable quality or reliability problem. The category with the highest claim rate is only marginally above the others, so it does not currently represent an urgent concern.

What I Recommend

The overall picture is positive: revenue is steady and broadly distributed across products, while warranty claims are consistent. The main priority is to validate the final month's revenue before treating it as a business signal.

- 1 Confirm whether the revenue drop in the final month reflects a real business change or simply incomplete data collection, before making any decisions based on it.
- 2 Continue investing across the current broad product range rather than concentrating budget on a small number of items, since no single product is currently carrying the business.
- 3 Keep an eye on the product category with the slightly higher warranty claim rate as a precaution, even though it is not yet a significant outlier compared to the rest.
